1000 Ljubljana, Slovenia

CONTENT

Why scatter neutrons?

Neutron (interaction with matter, comparison of structural probes)

Scattering (concepts, real and reciprocal space, scattering formulae)

Elastic scattering (nuclear, magnetic)

Inelastic scattering (nuclear, magnetic)

Instrumentation and Facilities (neutron production, fission reactor, spallation source, selecting the wavevector, detection)

Instruments (powder diffractometer, four-circle diffractometer, triple axis spectrometer, Time of flight spectrometer)

Analysis (Fullprof)

Examples on β -TeVO₄ compound

Powder neutron diffraction

Analysis of powder data

Magnetic structure refinement (powder/single crystal)

Single-crystal diffraction

Inelastic neutron scattering (powder, single crystal)

Using triple axis spectrometer

WHY SCATTER NEUTRONS?

- To determine the positions and motions of atoms in condensed matter

1994 Nobel prize awarded to Shull and Brockhouse

(see <http://www.nobel.se/physics/educational/poster/1994/neutrons.html>)

- Neutron advantages

- Wavelength comparable with interatomic spacings
- Kinetic energy comparable with that of atoms in a solid
- Weak interaction with matter makes relatively easy interpretation of the scattering data
- Deep penetration → bulk properties are measured (all sample at once)
- Isotopic sensitivity allows contrast variation
- **Neutron magnetic moment couples to magnetic field (B) → neutron “sees” unpaired electron spins**

- Neutron disadvantages

- Neutron sources are weak → low signals, need for large samples etc.
- Some elements (e.g. Cd, B, Gd) absorb strongly – become active during the experiment
- Kinematic restrictions (can't access all energy & momentum transfers)

THE 1994 NOBEL PRIZE IN PHYSICS

Clifford G. Shull & Bertram N. Brockhouse

S

Clifford G. Shull, MIT, Cambridge, Massachusetts, USA, receives one half of the 1994 Nobel Prize in Physics for the development of the neutron diffraction technique.

B

Bertram N. Brockhouse, McMaster University, Hamilton, Ontario, Canada, receives one half of the 1994 Nobel Prize in Physics for the development of neutron spectroscopy.

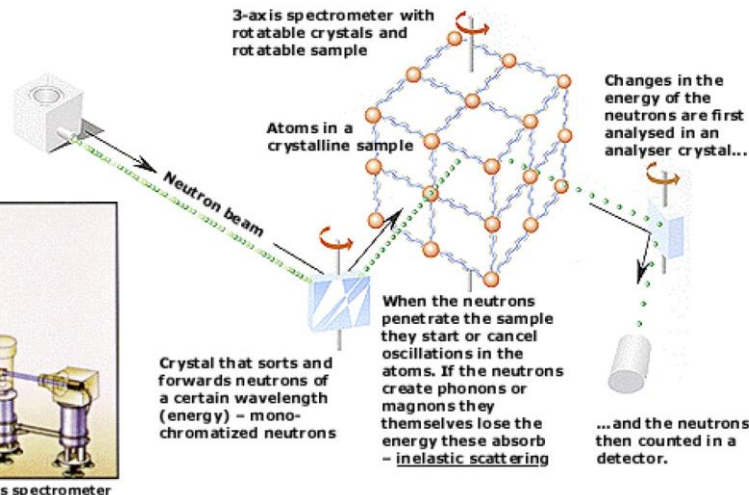

Neutrons show where atoms are...

When the neutrons collide with atoms in the sample material, they change direction (are scattered) – elastic scattering.

... and what atoms do.

3-axis spectrometer with rotatable crystals and rotatable sample

NEUTRON

- Composition: 1 up and 2 down quarks
- Massive: $m_n = 1.675 \times 10^{-27}$ kg – almost equal to proton
- No electric charge
- Spin: $S = 1/2$
- Magnetic moment: $\mu_n = -0.966 \times 10^{-26}$ J/T = $-1.042 \times 10^{-3} \mu_B$ (Bohr magneton)
= $-1.913 \mu_N$ (nuclear magneton)
- Kinetic energy (E), velocity (v), wave vector (k), wave length (λ), temperature (T) relations:

$$E = m_n v^2 / 2 = k_B T = (h k / 2\pi)^2 / 2m_n \quad k = 2\pi / \lambda = m_n v / (h / 2\pi) \quad \lambda = h / m_n v \quad (\text{de Broglie wavelength})$$

	E (meV)	T (K)	λ (nm)	v (m/s)	k (nm ⁻¹)
Cold	0.1 – 10	1 – 120	0.3 – 3	140 – 1000	2.2 – 22
Thermal	5 – 100	60 – 1000	0.1 – 0.4	1000 – 4000	15 – 70
Hot	100 – 500	1000 – 6000	0.04 – 0.1	4000 – 10000	70 – 155

INTERACTION WITH MATTER

Two types of interaction:

- with atomic nuclei: nuclear force – residual strong interaction
- with magnetic field: electromagnetic force – magnetic dipolar interaction

Sensitive to atomic position as well as magnetic moment

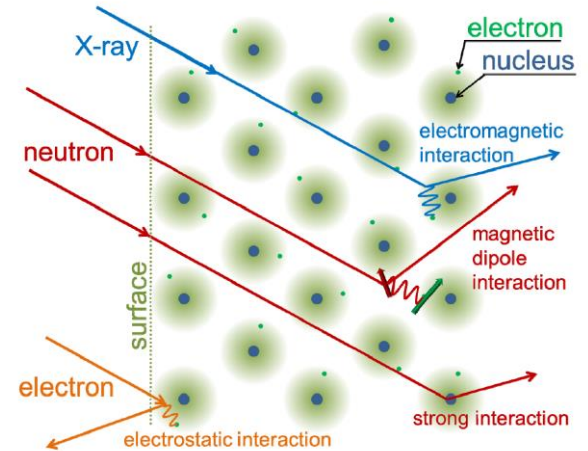

Nuclear force range $\sim 1 \text{ fm} \ll$ *neutron wavelength* leading to “point like” nuclear scattering

Magnetic interaction extends further leading to finite magnetic structure factor

Penetrate 1 cm to 1 m deep into the matter

- Good for scattering experiments
- Require thick shielding

When neutrons are absorbed γ -rays are emitted – massive shielding is required

INTERACTION WITH MATTER

Scattering cross sections are different then for x-rays

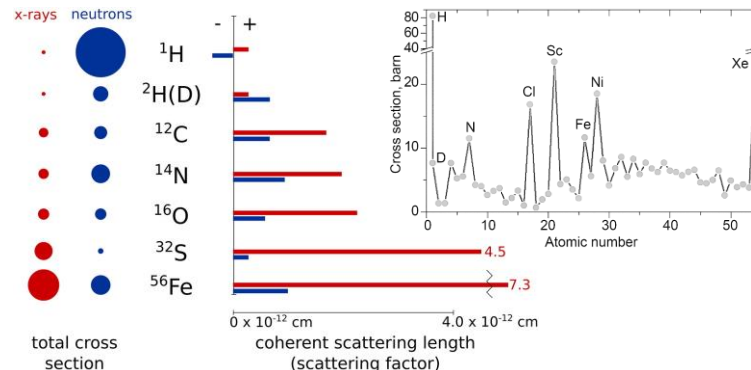

Two contributions:

- coherent scattering – depends on scattering vector
- Incoherent scattering – uniform in all directions

Several nuclei scatter very weakly, while several have very strong/dominant incoherent scattering

- Al is used for windows and sample containers
- V is used for sample containers and sensor calibration
- Difference between ^1H and ^2H in can be used for contrast
- Hydrogen samples are often deuterated ($^1\text{H} \rightarrow ^2\text{H}$)
- ^3He is used for detectors
- Heavy elements have high absorption and can get very active during experiments

<https://www.nist.gov/ncnr/neutron-scattering-lengths-list>

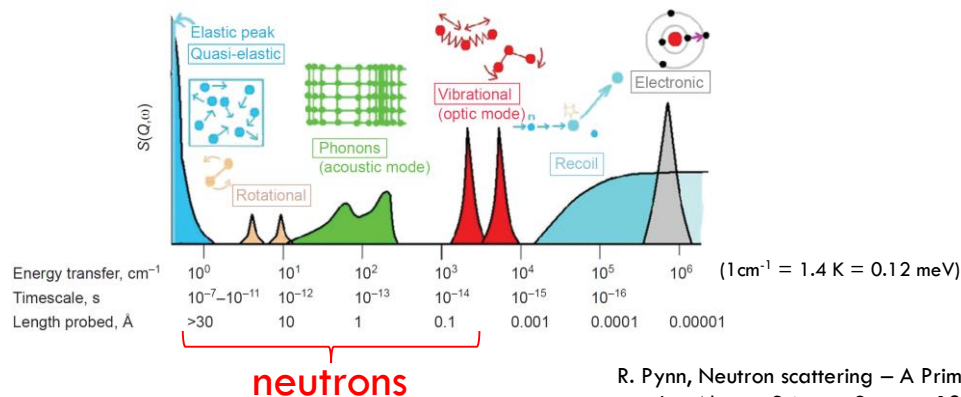

Nucleus	Cross section (1 barn = 10^{-24} cm^2)			
	Coherent	Incoherent	Total	Absorption
^1H	1.8	80.2	82.0	0.3
^2H	5.6	2.1	7.7	0
^3He	4.4	1.6	6.0	5333
^4He	1.3	0	1.3	0
C	5.6	0	5.6	0
N	11.0	0.5	11.5	1.9
O	4.2	0	4.2	0.0
Al	1.5	0.01	1.5	0.2
S	1.0	0	1.0	0.5
V	0.02	5.1	5.1	5.1
Fe	11.5	0.4	11.9	2.6
Co	0.8	4.8	5.6	37.2
Cu	7.5	0.5	8.0	3.8

COMPARISON OF STRUCTURAL PROBES

For optical/transmission techniques higher resolution is always related with more localized information of the structure

Scattering techniques provide statistically averaged information on the structure – not a real-space picture of particle positions

R. Pynn, Neutron scattering – A Primer, Los Alamos Science, Summer 1990

SCATTERING

Real space and Reciprocal space: $e^{i\vec{K}\cdot\vec{R}} = 1$

$$\begin{aligned}\hat{a}^* &= \frac{2\pi}{V} \hat{b} \times \hat{c} \\ \hat{b}^* &= \frac{2\pi}{V} \hat{c} \times \hat{a} \\ \hat{c}^* &= \frac{2\pi}{V} \hat{a} \times \hat{b}\end{aligned}$$

$$e^{i\vec{K}\cdot\vec{R}} = 1 \Rightarrow \hat{a}^* \cdot \hat{a} = \hat{b}^* \cdot \hat{b} = \hat{c}^* \cdot \hat{c} = 2\pi$$

$$\hat{a}^* \cdot \hat{b} = \dots = 0$$

$$\vec{K} = 2\pi \left(\frac{h}{a}, \frac{k}{b}, \frac{l}{c} \right) - \text{reciprocal lattice vector}$$

SCATTERING

Real space and Reciprocal space: $e^{i\vec{K}\cdot\vec{R}} = 1$

Reciprocal space

$$\hat{a}^* = \frac{2\pi}{V} \hat{b} \times \hat{c}$$

$$\hat{b}^* = \frac{2\pi}{V} \hat{c} \times \hat{a}$$

$$\hat{c}^* = \frac{2\pi}{V} \hat{a} \times \hat{b}$$

$$e^{i\vec{K}\cdot\vec{R}} = 1 \Rightarrow \hat{a}^* \cdot \hat{a} = \hat{b}^* \cdot \hat{b} = \hat{c}^* \cdot \hat{c} = 2\pi$$

$$\hat{a}^* \cdot \hat{b} = \dots = 0$$

$$\vec{K} = 2\pi\left(\frac{h}{a}, \frac{k}{b}, \frac{l}{c}\right) - \text{reciprocal lattice vector}$$

SCATTERING

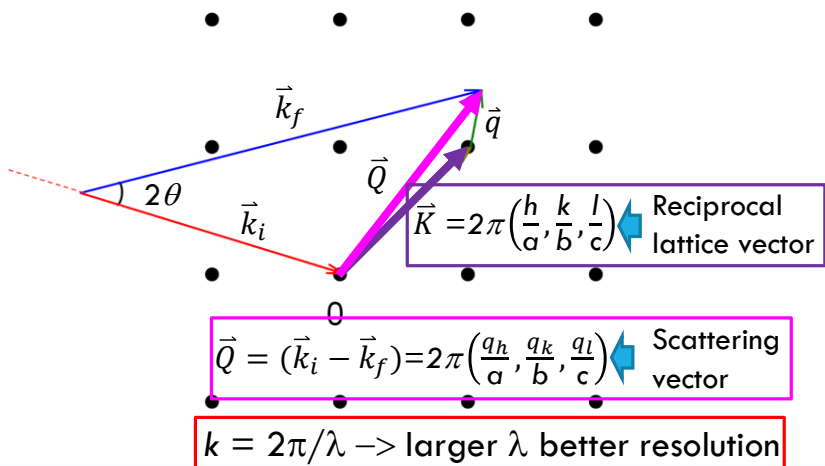

- Elastic scattering ($k_f = k_i = k$)

$$\sin\theta = \frac{Q/2}{k}$$

Reciprocal space

- Inelastic scattering ($k_f \neq k_i$)

$$E = \hbar\omega = E_i - E_f = \frac{\hbar}{2m}(k_i^2 - k_f^2); \quad Q^2 = k_i^2 + k_f^2 - 2k_i k_f \cos 2\theta$$

SCATTERING

- Elastic scattering ($k_f = k_i = k$)

$$\sin \theta = \frac{Q/2}{k}$$

Reciprocal space

$$\vec{K} = 2\pi \left(\frac{h}{a}, \frac{k}{b}, \frac{l}{c} \right) \leftarrow \text{Reciprocal lattice vector}$$

$$\vec{Q} = (\vec{k}_i - \vec{k}_f) = 2\pi \left(\frac{qh}{a}, \frac{qk}{b}, \frac{ql}{c} \right) \leftarrow \text{Scattering vector}$$

$$k = 2\pi/\lambda \rightarrow \text{larger } \lambda \text{ better resolution}$$

- Inelastic scattering ($k_f \neq k_i$)

$$E = \hbar\omega = E_i - E_f = \frac{\hbar}{2m} (k_i^2 - k_f^2); \quad Q^2 = k_i^2 + k_f^2 - 2k_i k_f \cos 2\theta$$

SCATTERING FORMULAE

Basic quantity: **differential cross section** $\frac{d\sigma}{d\Omega} = \frac{\text{numbers of neutrons scattered per second into } d\Omega}{(\text{number of incident neutrons per area unit per second}) \cdot d\Omega}$

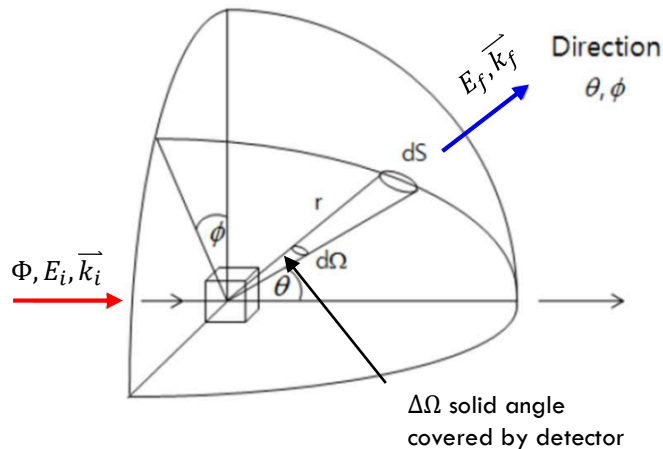

- Incident neutron flux: $\Phi = \text{number of incident neutrons per area unit per second}$
- Cross section: $\sigma = \text{total number of neutrons scattered per second} / \Phi$
- Dimensions: $\left[\frac{d\sigma}{d\Omega}\right] = \frac{1}{[\Delta\Omega] [t] [\Phi]} = \text{area} ([L]^2 - \text{dimensions})$

Calculation of $\frac{d\sigma}{d\Omega}$ through Fermi's Golden Rule: $\frac{d\sigma}{d\Omega} = \frac{W}{\Phi}$

Transition rate: $W = \frac{2\pi}{\hbar} \underbrace{|\langle \vec{k}_f | V | \vec{k}_i \rangle|^2}_{\text{interaction}} \underbrace{\rho_f(E)}_{\text{density of final states}}$ matrix element (contains physics)

- $|k_i\rangle = \frac{1}{\sqrt{L^3}} e^{i\vec{k}_i \cdot \vec{r}}$
- $|k_f\rangle = \frac{1}{\sqrt{L^3}} e^{i\vec{k}_f \cdot \vec{r}}$
- $\rho_f(E) = \left(\frac{L}{2\pi}\right)^3 \frac{d\vec{k}_f}{dE} = \left(\frac{L}{2\pi}\right)^3 k_f^2 \frac{dk_f}{dE} d\Omega = \left(\frac{L}{2\pi}\right)^3 \frac{m_n k_f}{\hbar^2} d\Omega$
- density of states in k-space
- $d\vec{k}_f = k_f^2 dk_f d\Omega$
- $\frac{dE}{dk_f} = \frac{\hbar^2 k_f}{m_n}$

Incident neutron flux: $\Phi = \frac{\text{velocity}}{L^3} = \frac{\hbar^2 k_i}{m_n L^3}$

$$\frac{d\sigma}{d\Omega} = \frac{k_f}{k_i} \left(\frac{m_n L^3}{2\pi \hbar^2}\right)^2 |\langle \vec{k}_f | V | \vec{k}_i \rangle|^2$$

ELASTIC NUCLEAR SCATTERING

For elastic scattering: $k_i = k_f$

$$\frac{d\sigma}{d\Omega} = \frac{W}{\Phi} = \left(\frac{m_n}{2\pi\hbar^2}\right)^2 \left| \int V e^{i(\vec{k}_i - \vec{k}_f) \cdot \vec{r}} d\vec{r} \right|^2 = \left(\frac{m_n}{2\pi\hbar^2}\right)^2 \left| \int V e^{i\vec{Q} \cdot \vec{r}} d\vec{r} \right|^2$$

“Born approximation”: taking scattered wave function as a plane wave

For short-range (nuclear) force, approximate “point-like” potential:

$$V(\vec{r}) = \frac{2\pi\hbar^2}{m_n} b \delta(\vec{r} - \vec{R});$$

- Position of the nucleus: \vec{R}
- Scattering length b depends on the details of the nuclear structure and varies greatly (table in previous slide)

For **single nucleus**: $\frac{d\sigma}{d\Omega} = |b|^2 \rightarrow$ Total cross section: $\sigma = \int \frac{d\sigma}{d\Omega} d\Omega = 4\pi b^2$

Lattice of nuclei:

$$V(\vec{r}) = \frac{2\pi\hbar^2}{m_n} \sum_{\vec{R}} b_{\vec{R}} \delta(\vec{r} - \vec{R}); \quad b_{\vec{R}}: \text{scattering length of nucleus at site } \vec{R}$$

$$\frac{d\sigma}{d\Omega} = \left| \int \sum_{\vec{R}} b_{\vec{R}} \delta(\vec{r} - \vec{R}) e^{i\vec{Q} \cdot \vec{r}} d\vec{r} \right|^2 = \left| \sum_{\vec{R}} b_{\vec{R}} e^{i\vec{Q} \cdot \vec{R}} \right|^2 \leftarrow \text{function of } \vec{Q}$$

Real space

ELASTIC NUCLEAR SCATTERING

For most \vec{Q} , matrix elements are very small because phase factors from different nuclei cancel out. Matrix element is large only when $\vec{Q} = \vec{K}$, where \vec{K} is “reciprocal lattice vector” defined as $e^{i\vec{K}\cdot\vec{R}} = 1$.

The constructive interference leads to a huge enhancement, i.e., “Bragg peak”

Using $\left| \sum_{\vec{R}} e^{i\vec{Q}\cdot\vec{R}} \right|^2 = N \frac{(2\pi)^3}{v_0} \sum_{\vec{K}} \delta(\vec{Q} - \vec{K})$

- Total number of unit cells: N
- Volume of unit cell: v_0

For all nuclei being identical:

$$\frac{d\sigma}{d\Omega} = b^2 \frac{N(2\pi)^3}{v_0} \sum_{\vec{K}} \delta(\vec{Q} - \vec{K})$$

Nuclear Bragg diffraction for unit cell with several atoms with basis vectors \vec{d}

$$\frac{d\sigma}{d\Omega} = \frac{N(2\pi)^3}{v_0} \sum_{\vec{K}} \delta(\vec{Q} - \vec{K}) |F_N(\vec{K})|^2,$$

where $F_N(\vec{K}) = \sum_{\vec{d}} e^{i\vec{Q}\cdot\vec{d}} b_{\vec{d}}$ is the “nuclear structure factor”.

Reciprocal space

Real space

ELASTIC NUCLEAR SCATTERING

Two contributions

$$\frac{d\sigma}{d\Omega} = N \frac{(2\pi)^3}{v_0} \langle b \rangle^2 \sum_{\vec{K}} \delta(\vec{Q} - \vec{K}) + N[\langle b^2 \rangle - \langle b \rangle^2]$$

"coherent" scattering "incoherent" scattering

Coherent scattering carries information about the crystal structure and depends on \vec{Q} .

Incoherent scattering carries information about the grain sizes and is for large grains (even for most powders) almost uniform across the Q space.

Both contributions strongly differ between different nuclei – see table at the beginning of the presentation.

ELASTIC MAGNETIC SCATTERING

From the Fermi's Golden Rule, similar as in nuclear neutron scattering

$$\frac{d\sigma}{d\Omega} = \left(\frac{m_n}{2\pi\hbar^2}\right)^2 \left| \langle \vec{k}_f m_f | H_m | \vec{k}_i m_i \rangle \right|^2 \text{ with } H_m = -\vec{\mu}_n \cdot \vec{H}_e$$

- Neutron spin state: $|m\rangle = |\pm 1\rangle$
- Electron magnetic field: \vec{H}_e

Vector potential of dipole field (classical electromagnetism)

$$\vec{A}_e = \frac{\mu_0}{4\pi} \frac{\vec{\mu}_e \times \vec{r}}{r^3} = \frac{\mu_0}{4\pi} \vec{\mu}_e \times \vec{\nabla} \frac{1}{r}; \quad \vec{H}_e = \vec{\nabla} \times \vec{A}_e = \frac{\mu_0}{4\pi} \vec{\nabla} \times \left(\vec{\mu}_e \times \vec{\nabla} \frac{1}{r} \right)$$

$$\frac{d\sigma}{d\Omega} = \left(\frac{m_n}{2\pi\hbar^2}\right)^2 (2\gamma\mu_N\mu_B)^2 \left| \langle \vec{k}_f m_f | \vec{\sigma}_n \cdot \vec{\nabla} \times \left(\vec{s}_e \times \vec{\nabla} \frac{1}{r} \right) | \vec{k}_i m_i \rangle \right|^2$$

- Collecting all prefactors: $\left(\frac{m_n}{2\pi\hbar^2}\right)^2 (2\gamma\mu_N\mu_B)^2 \left(\frac{\mu_0}{4\pi}\right)^2 (4\pi)^2 = (\gamma r_0)^2$
- Classical electron radius: $r_0 = 2.8 \times 10^{-15} \text{m}$

Finally we obtain:
$$\frac{d\sigma}{d\Omega} = (\gamma r_0)^2 \left| \langle m_f | \vec{\sigma}_\uparrow \cdot \vec{s}_{e\perp} | m_i \rangle \right|^2$$

neutron beam polarization

Using the relation:

$$\begin{aligned} \int \frac{d\vec{p}}{|\vec{p}|^2} e^{i\vec{p} \cdot \vec{r}} &= 2\pi \int_0^\infty d|\vec{p}| \int_{-1}^1 e^{i|\vec{p}||\vec{r}| \cos \Theta} d(\cos \Theta) \\ &= 2\pi \int_0^\infty d|\vec{p}| \frac{\sin|\vec{p}||\vec{r}|}{|\vec{p}||\vec{r}|} = \frac{2\pi^2}{|\vec{r}|} \end{aligned}$$

The vector product can be rewritten as:

$$\begin{aligned} \vec{\nabla} \times \left(\vec{s}_e \times \vec{\nabla} \frac{1}{r} \right) &= \frac{1}{2\pi^2} \int \frac{d\vec{p}}{|\vec{p}|^2} \vec{\nabla} \times \left(\vec{s}_e \times \vec{\nabla} \right) e^{i\vec{p} \cdot \vec{r}} \\ &= \frac{1}{2\pi^2} \int \vec{p} \times \left(\vec{s}_e \times \vec{p} \right) e^{i\vec{p} \cdot \vec{r}} d\vec{p} \end{aligned}$$

And finally:

$$\begin{aligned} \left\langle \vec{k}_f \left| \vec{\nabla} \times \left(\vec{s}_e \times \vec{\nabla} \frac{1}{r} \right) \right| \vec{k}_i \right\rangle &= \frac{1}{2\pi^2} \int d\vec{r} e^{-i\vec{Q} \cdot \vec{r}} \int d\vec{p} \vec{p} \times \left(\vec{s}_e \times \vec{p} \right) e^{i\vec{p} \cdot \vec{r}} \\ &= 4\pi \vec{Q} \times \left(\vec{s}_e \times \vec{Q} \right) \\ &\equiv \vec{s}_{e\perp} \end{aligned}$$

When the relation:

$$\frac{1}{(2\pi)^2} \int d\vec{r} e^{-i(\vec{p}-\vec{Q}) \cdot \vec{r}} = \delta(\vec{p}-\vec{Q}) \text{ is used.}$$

$\vec{s}_{e\perp}$ is magnetic component perpendicular to \vec{Q} !

ELASTIC MAGNETIC SCATTERING

For **unpolarized** neutrons we have to average across all neutron spin states $|m\rangle$. For convenience we choose neutron quantization axis $\hat{z} \parallel \vec{s}_{e\perp}$:

$$\langle m_f | \vec{\sigma} \cdot \vec{s}_{e\perp} | m_i \rangle = s_{e\perp} \langle m_f | \sigma_z | m_i \rangle = \begin{cases} s_{e\perp} & \text{if } m_f = m_i \\ 0 & \text{otherwise} \end{cases}$$

The cross section for a **single electron** at rest for an unpolarized neutron beam is:

$$\frac{d\sigma}{d\Omega} = (\gamma r_0)^2 |s_{e\perp}|^2; \text{ with } \vec{s}_{e\perp} \text{ the projection of the electron spin perpendicular to } \vec{Q}$$

Generalization for **an atom**:

$$\frac{d\sigma}{d\Omega} = (\gamma r_0)^2 |\hat{\eta}_\perp|^2 |f(\vec{Q})|^2 = (\gamma r_0)^2 [1 - (\hat{\eta} \cdot \vec{Q})^2] |f(\vec{Q})|^2;$$

- **Magnetic form factor:** $f(\vec{Q}) = \frac{1}{2\mu_B} \int \mathcal{M}(\vec{r}) e^{i\vec{Q} \cdot \vec{r}}$
- Magnetic dipole moment density due to unpaired electrons in the atom: $\vec{\mathcal{M}}(\vec{r}) = \mathcal{M}(\vec{r}) \hat{\eta}$

Generalization for **collinear magnets** (ordered):

$$\frac{d\sigma}{d\Omega} = (\gamma r_0)^2 [1 - (\hat{\eta} \cdot \vec{Q})^2] N \frac{(2\pi)^3}{v_0} \sum_{\vec{K}_M} \delta(\vec{Q} - \vec{K}_M) |F_M(\vec{K}_M)|^2$$

- Magnetic reciprocal lattice vector: \vec{K}_M
- Magnetic structure factor: $F_M(\vec{Q}) = \sum_{\vec{d}} (\pm) e^{i\vec{Q} \cdot \vec{d}} f_{\vec{d}}(\vec{Q})$, sign \pm depend on orientation in respect to $\hat{\eta}$ at \vec{d} .

Real space

ELASTIC MAGNETIC SCATTERING

One-dimensional ferromagnet

Nuclear and magnetic unit cells are identical

$$\vec{K}_M = \vec{K}_N = \frac{2\pi}{a} n; \text{ where } n \text{ is integer}$$

One-dimensional antiferromagnet

Basis: $\vec{d}_1 = 0, \vec{d}_2 = \hat{a}$,
 Mag. structure factor: $f_{\vec{d}_2}(\vec{Q}) = -f_{\vec{d}_1}(\vec{Q})$

Magnetic unit cell is twice as large as nuclear unit cell

$$\vec{K}_M = \frac{\pi}{a} n \neq \vec{K}_N = \frac{2\pi}{a} n \rightarrow |F_M|^2 = \left| \sum_{\vec{d}} e^{i\vec{Q}\cdot\vec{d}} f_{\vec{d}}(\vec{Q}) \right|^2 = |f(\vec{Q})|^2 |1 - e^{iQa}|^2$$

$$= 4|f(\vec{Q})|^2 \left(\sin \frac{Qa}{2} \right)^2 = \begin{cases} 4|f(\vec{Q})|^2 & \text{for } n \text{ odd} \\ 0 & \text{for } n \text{ even} \end{cases}$$

SCATTERING SUMMARY

Nuclear scattering:

- Unit cell – position of reflections
- Position of the atoms in the unit cell – peak intensities
- Types of atoms – peak intensities

Magnetic scattering:

- Magnetic unit cell/modulation – peak position
- Type of magnetic order – peak position
- Orientation of magnetic moments – peak intensities
- Size of magnetic moments – peak intensities

INELASTIC SCATTERING

$$\frac{d^2\sigma}{d\Omega dE} = \frac{\text{numbers of neutrons scattered per second into } d\Omega \text{ \& } dE}{\Phi d\Omega dE}$$

Conservation of energy

$$\frac{d^2\sigma(\vec{Q}, E)}{d\Omega dE} = \frac{k_f}{k_i} \underbrace{|\langle \vec{k}_f m_f | V | \vec{k}_i m_i \rangle|^2}_{\text{Matrix element - contains physics}} \delta(E_i - E_f + E)$$

Nuclear scattering

$$\frac{d^2\sigma}{d\Omega dE} = N \frac{k_f}{k_i} b^2 S(\vec{Q}, \omega), \quad \omega = E/\hbar$$

$$S(\vec{Q}, \omega) = \frac{1}{2\pi\hbar N} \int_{-\infty}^{\infty} \sum_{j,j'} e^{-i\omega t} \langle e^{i\vec{Q}\cdot\vec{r}_j(0)} e^{i\vec{Q}\cdot\vec{r}_{j'}(t)} \rangle dt$$

Magnetic scattering

$$\frac{d^2\sigma}{d\Omega dE} = \left(\frac{g_n r_0}{2}\right)^2 f^2(\vec{Q}) e^{-2W(\vec{Q}, T)} \frac{k_f}{k_i} \sum_{\alpha\beta} (\delta_{\alpha\beta} - \hat{Q}_\alpha \hat{Q}_\beta) S^{\alpha\beta}(\vec{Q}, \omega)$$

$$S^{\alpha\beta}(\vec{Q}, \omega) = \frac{1}{2\pi\hbar} \int_{-\infty}^{\infty} \sum_{j,j'} e^{i\vec{Q}\cdot(\vec{r}_j - \vec{r}_{j'})} e^{-i\omega t} \langle S_{j'}^\alpha(0) S_j^\beta(t) \rangle dt$$

b – scattering length

N – number of atoms

S – scattering function, which is Fourier transforms of time dependent pair correlations functions of either atomic or spin component

f – magnetic form factor (Bessel functions, decays with Q)

There is no form factor for nuclear scattering, as the nucleus can be considered as a point compared to the neutron wavelength!

W – Debye-Waller factor accounts for attenuation of coherent neutron scattering due to thermal motion of atoms

$g_n = 1.913$

$r_0 = 2.8 \times 10^{-15}$ m is the classical electron radius

INELASTIC SCATTERING

Expressions for $S(\vec{Q}, \omega)$ can be worked out for a number of cases e.g.:

- Excitation or absorption of one quantum of lattice vibrational energy (phonon)
- Various models for atomic motions in liquids and glasses
- Various models of atomic & molecular translational & rotational diffusion
- Rotational tunnelling of molecules
- Single particle motions at high momentum transfers
- Transitions between crystal field levels
- Magnons and other magnetic excitations such as spinons

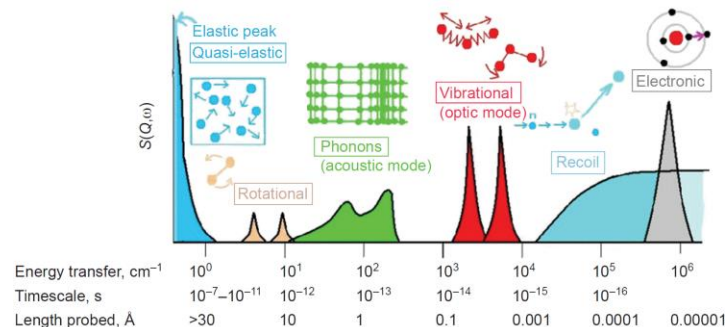

Inelastic neutron scattering reveals details of the shapes of interaction potentials in materials

Nuclear scattering function

$$S(\vec{Q}, \omega) = \frac{1}{2\pi\hbar N} \int_{-\infty}^{\infty} \sum_{j,j'} e^{-i\omega t} \langle e^{i\vec{Q}\cdot\vec{r}_j(0)} e^{i\vec{Q}\cdot\vec{r}_{j'}(t)} \rangle dt$$

Magnetic scattering function

$$S^{\alpha\beta}(\vec{Q}, \omega) = \frac{1}{2\pi\hbar} \int_{-\infty}^{\infty} \sum_{j,j'} e^{i\vec{Q}\cdot(\vec{r}_j - \vec{r}_{j'})} e^{-i\omega t} \langle S_{j'}^{\alpha}(0) S_{j'}^{\beta}(t) \rangle dt$$

neutrons

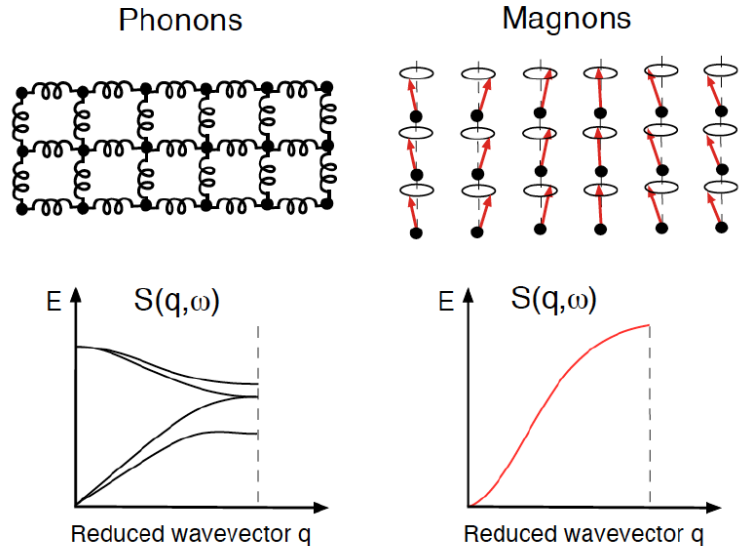

INELASTIC SCATTERING

Lattice waves => collective acoustic and optic lattice vibrations – **Phonons**

Spin-waves => collective magnetic excitations associated to the in-phase precession of the spin moments – **Magnons**

Phonons and magnons are quasi-particles (excitations) associated to the lattice and spin excitations

- They are characterized by a frequency ω and a wavevector \vec{q}
- Dispersion relationship between energy $\hbar\omega$ and momentum $\hbar\vec{q}$

MAGNETIC SCATTERING SUMMARY

The magnetic moment of the neutron interacts with B fields caused, for example, by unpaired electron spins in a material

- Nuclear and magnetic scattering have similar magnitudes
- Both spin and orbital angular momentum of electrons contribute to B
- Magnetic scattering involves a form factor – FT of electron spatial distribution
 - Electrons are distributed in space over distances comparable to neutron wavelength
 - Elastic magnetic scattering of neutrons can be used to probe electron distributions
- Magnetic scattering depends *only* on component of B perpendicular to Q
- For neutrons spin polarized along a direction z (defined by applied H field):
 - Correlations involving B_z do not cause neutron spin flip
 - Correlations involving B_x or B_y cause neutron spin flip
- Coherent & incoherent nuclear scattering also affects spin polarized neutrons

INSTRUMENTATION AND FACILITIES

What are basic requirements to perform neutron scattering?

- A source of neutrons
- A method to choose the wavevector of the incident neutrons k_i
- A sample
- A method to determine the wavevector of the scattered neutrons k_f (not needed for elastic scattering)
- A neutron detector

NEUTRON PRODUCTION

Fission reactor:

- Chain reaction: neutron + $^{235}\text{U} \rightarrow$ Fission products + 2.4 neutrons (average)
- Very intense source ($\sim 10^{12}$ n/s per megawatt in research reactors)

Spallation source:

- No chain reaction – pulsed or continuous operation.
- Protons, accelerated by particle accelerator, strike a target made of heavy elements (e.g. mercury), where excited nuclei emit neutrons

Moderators:

- Neutrons have very high energies (~ 1 MeV) so they must be slowed down
 - Liquide graphite for hot neutrons
 - Water or heavy water for thermal neutrons
 - Liquid deuterium for cold neutrons

Neutron guides:

- From the source neutrons are guided to instruments by evacuated tubes
- These may be coated from the inside by supermirror multilayers

Calculated, from G.J. Russell, Spallation physics—an overview, Proceedings of ICANS-XI

NEUTRON FACILITIES

Large scale facilities

- Instruments are arranged around the neutron source
- Complex operation requires support from a local contact
- A variety of sample environments (cryostats, magnets, ...)
- One needs to apply for neutron beam time

PSI, Villigen, Switzerland

ILL, Grenoble, France

FISSION REACTOR

Example: Institute Laue Langevin (ILL),
Grenoble, France

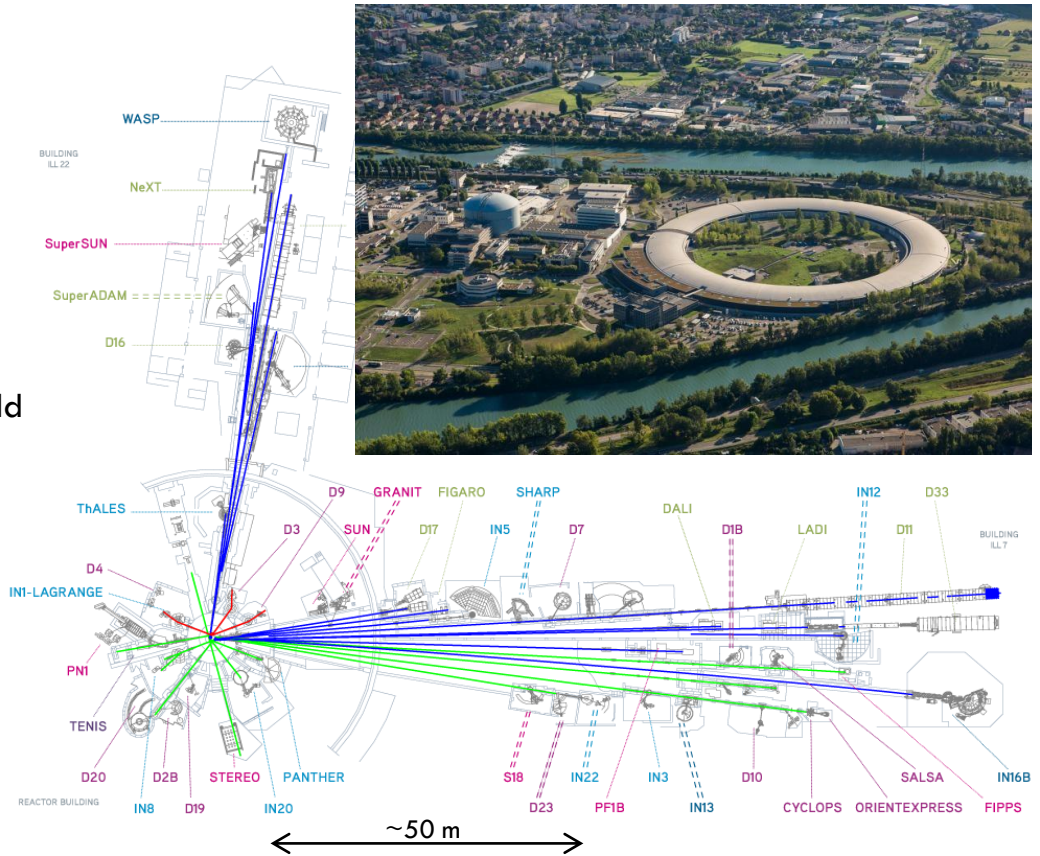

- Leading neutron research facility in the world
- Most intense flux in the moderator region $10^{15} \text{ s}^{-1}\text{cm}^{-2}$, thermal power of 58.3 MW

FISSION REACTOR

Example: Institute Laue Langevin (ILL),
Grenoble, France

- Leading neutron research facility in the world
- Most intense flux in the moderator region $10^{15} \text{ s}^{-1} \text{ cm}^{-2}$, thermal power of 58.3 MW
- About 40 instruments
- Two calls for proposals, one in spring and one in autumn

SPALLATION SOURCE

Example: ISIS, Rutherford Appleton Laboratory, UK

- Pulsed neutron spallation source
- Two targets
- Targets made of Tungsten is being replaced every 2 to 5 years
- 800 MeV protons at 50 Hz
- Short pulses of $\sim 0.5 \mu\text{s}$
- cca 25 instruments

SELECTING THE WAVEVECTOR

Monochromators

- Bragg reflection of a single crystal
- Ferromagnetic crystal – polarized neutrons
- Neutron energy determined by physical limitations

Disc choppers

- Disc with a hole
- Typically two one after another
- Very versatile, yet limited by rotation speed
- Better for lower energy neutrons

Fermi choppers

- Drum with a hole
- Sheets of absorbing material
- Curved – optimized for specific energy ranges
- Rotate up to 600 Hz
- Also for higher energy neutrons 15 meV to 2 eV

DETECTION

- ${}^3\text{He} + n \rightarrow {}^3\text{H} + p + 0.764 \text{ MeV}$
- Ionization caused by triton and proton is collected on an electrode
- 70% of neutrons are absorbed when the product of:
gas pressure x thickness x neutron wavelength = 16 atm x cm x Å
- Modern detectors are often “position sensitive” – charge division is used to determine where the ionization cloud reached the cathode
- Most detectors need bulky shielding as they are also sensitive to γ -rays

The IN5 Large area Multitube at ILL, France
12 modules of 32 tubes (+ 1 spare)
Distance sample – detector = 4 m
Each tube is 2.54 cm diameter, 3 m long
Volume of ${}^3\text{He}$ = 600 litres * Pressure (4.5 bar) = 2700 litres

The first MultiTube (in operation at LLB, France)

HOW IS NEUTRON SCATTERING MEASUREED?

Large penetration depth

- Large samples
- Massive detectors, shielding, ...
- Slow movements of instruments

Powder

- Large samples – several grams
- Typically collect broad spectrum - fast
- Measure overlapping contributions from all phases

Single crystal

- Much larger samples compared to x-ray, SQUID, specific heat, ...
- Detection of single reflections – slow
- Phase specific – by choosing which reflections are being measured

Time-of-Flight – pulsed source

Monochromator – continuous source

POWDER DIFFRACTOMETER

Powder = Many tiny crystals

- 1 cm³ of 10 μm crystallites = 10⁹ particles,
- 1 cm³ of 1 μm crystallites = 10¹² particles

All orientations of crystallites possible

Single-crystal reciprocal lattice is smeared into spherical shells

Typically data at all angles are collected simultaneously

If several phases are present, all contributions sum up

Sample container: Al, V

FOUR-CIRCLE DIFFRACTOMETER

Single crystal measurements

Four rotations are possible:

- 2θ – position of the detector in respect to incident beam
- ω – rotation of the crystal within the scattering plane
- ϕ – rotation of the crystal around the pin
- χ – rotation of the sample out of scattering plane

Sample glued or fixed by Al wires to an Al pin

At least crystal unit cell has to be known

Single crystal has to be aligned precisely to Bragg reflection – to start: 2θ is set for the strong reflection and then the corresponding direction is aligned by eye to bisect the incident and scattered beam, i.e., to point along Q vector

U-matrix connects the reciprocal space with ϕ , χ , and ω angles

TRIPLE AXIS SPECTROMETER

For single-crystals

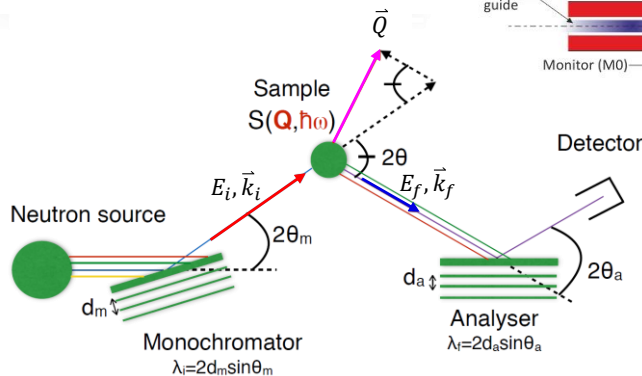

Explore energy transfer, i.e., dispersion relations

$$\hbar\omega = E_i - E_f = \frac{\hbar^2}{2m} (k_i^2 - k_f^2)$$

$$Q^2 = k_i^2 + k_f^2 - 2k_i k_f \cos 2\theta$$

It allows measurement of the scattering function at any point in energy and momentum space physically accessible by the spectrometer

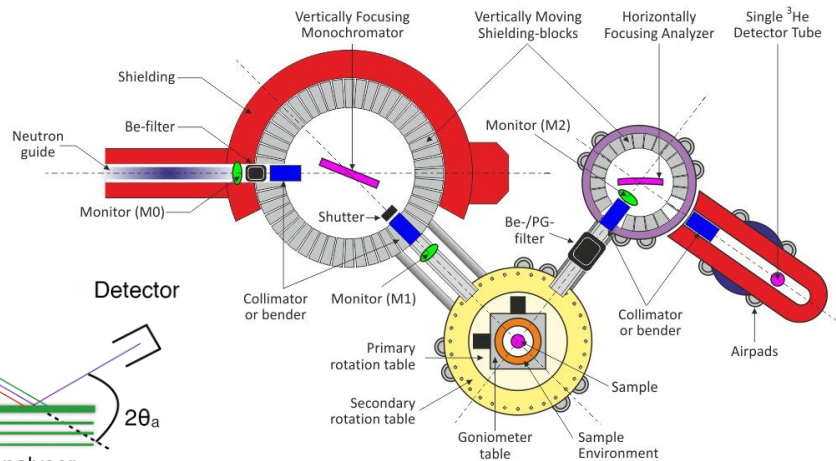

Typical limitation is the scattering plane

Real space

Reciprocal space

TASP PSI, Switzerland

TIME OF FLIGHT SPECTROMETER

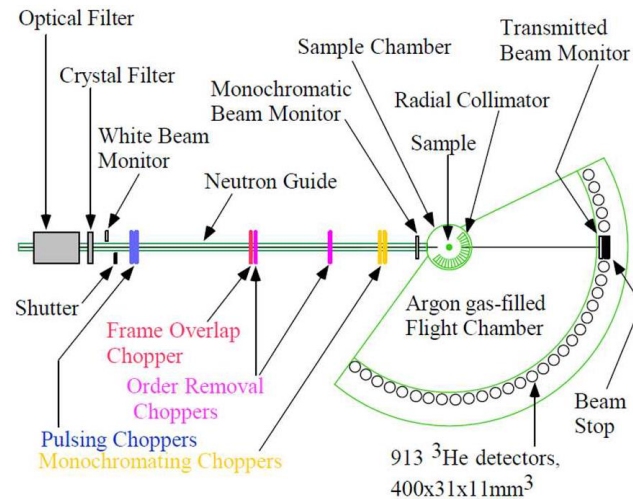

The time of flight spectrometer determines neutron energy by measuring its time of flight from one point to another.

The beams are monochromated using several choppers rotating at different frequencies allowing only neutrons at certain velocity can pass through.

Since we know the distance between the sample and detectors and can measure the time for neutron to fly from the sample to the detector, we then can calculate the energy of scattered neutrons.

The direction of momentum can be figured out from the detector angle.

Time-of-flight method is powerful in that it can map out the huge Q-E space at a time.

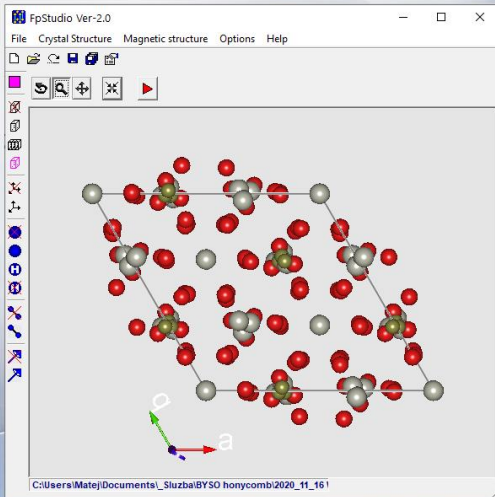

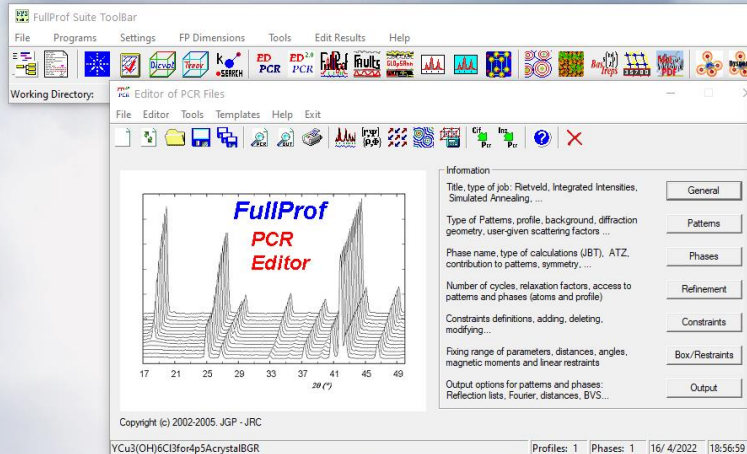

ANALYSIS - FULLPROF

Probably most widely used open source suite for analysis of diffraction data by Juan Rodríguez-Carvajal, Institut Laue-Langevin, Grenoble, France (<http://www.ill.eu/sites/fullprof/>)

- **WinPLOT**: Programs for visualising powder diffraction patterns from a large number of instruments (almost each instrument has a unique file structure). Fitting independent peaks (CW and TOF)
- **FullProf**: Crystal and magnetic structure refinement, powder/single crystals, polarised neutrons, constant wavelength, TOF, energy dispersive, multiple patterns, simulated annealing for solving crystal and magnetic structures (integrated and profile intensities).
- **EdPCR**: Editor of the FullProf input control file
- **SuperCell/K_Search**: Program for searching propagation vectors
- **BasIREPS**: Program for calculating basis functions of irreducible representations of space groups. Useful for determining magnetic structures .
- **Fp_Studio**: Program for visualising crystal and magnetic structures
- And more: Fourier/GFourier and Bond_Str/GBond_Str. Fourier and distance/angle calculations; Check_Group: Program for getting the space group (powders and single crystals) Datared/GDatared: Program for single crystal data reduction; Mol_tpcr: console utility for creating Rigid body groups

EXAMPLE: $\text{YCu}_3(\text{OH})_6\text{Cl}_3$

Starting point

- Crystal structure
- Basic magnetic properties ($\text{Cu}^{2+} S = 1/2$)
- Magnetic ordering at 15 K

Our approach to determine the magnetic order

- **Experiment:** Powder neutron diffraction to see if long-range magnetic order develops
- **Analysis:** Indexation of magnetic reflections, attempt to refine the magnetic structure

KAGOME LATTICE IN $\text{YCu}_3(\text{OH})_6\text{Cl}_3$

Kagome lattice Cu^{2+} $S = 1/2$

Antiferromagnetic
interaction

Geometric
frustration

Without anisotropies spin-liquid ground state is expected

Anisotropies may stabilize magnetic order

MAGNETIC SUSCEPTIBILITY

High-temperature imply Curie Weiss temperature
 $\theta_{CW} = -99$ K strong interactions

Magnetic order develops at $T_N = 15$ K

Strong frustration $T_N/\theta_{CW} = 0.15$

POWDER DIFFRACTION

We performed powder diffraction at several temperatures above and below T_N

At 8 and 1.5 K additional reflections emerge

A clear sign of magnetic order

K VECTOR SEARCH

When magnetic reflections are identified, one can start thinking about the magnetic order.

Begin with identification of magnetic ordering (wave) vector (K vector) using K-search.

Input:

- Space group
- Lattice parameters
- Neutron wavelength and tolerance
- Incommensurability/Commensurability
- K range
- Precision

Output:

- List of 10 best solutions
- Calculated and observed angles for the best solution

REPRESENTATION ANALYSIS

If positions of the observed magnetic reflections match the calculated ones, i.e., *if the derived magnetic wave vector is correct, one can try to refine magnetic structure.*

Starting point is **representation analysis** – the crystal-structure space group and magnetic wave vector impose symmetry restrictions for possible magnetic structures (in case of second-order magnetic transition) – *using Basreps.*

One can derive magnetic group (little group) and its possible irreducible representations (IRR), on of which should in principle describe the emergent magnetic order.

REPRESENTATION ANALYSIS

If positions of the observed magnetic reflections match the calculated ones, i.e., if the derived magnetic wave vector is correct, one can try to refine magnetic structure.

Starting point is **representation analysis** – the crystal-structure space group and magnetic wave vector impose symmetry restrictions for possible magnetic structures (in case of second-order magnetic transition) – using **Basreps**.

One can derive magnetic group (little group) and its possible irreducible representations (IRR), on of which should in principle describe the emergent magnetic order.

REPRESENTATION ANALYSIS

For (0 0 0.5) vector and magnetic (Cu^{2+}) site at (0.5, 0.5, 0.5) three irreducible representations (IRR) of space group P-3m1 are possible

Γ_2 and Γ_4 are one dimensional, while Γ_5 is two dimensional, each can have more basis vectors, which describes the relation of the magnetic components on different sites

irrep	Basis vector	Atom 1			Atom 2			Atom 3		
		m_a	m_b	m_c	m_a	m_b	m_c	m_a	m_b	m_c
Γ_2	ψ_2^1	$\frac{1}{\sqrt{3}}$	$-\frac{1}{\sqrt{3}}$	0	$\frac{1}{\sqrt{3}}$	$\frac{2}{\sqrt{3}}$	0	$-\frac{2}{\sqrt{3}}$	$-\frac{1}{\sqrt{3}}$	0
	ψ_2^2	0	0	1	0	0	1	0	0	1
Γ_4	ψ_4^1	1	1	0	-1	0	0	0	-1	0
Γ_5	ψ_5^1	1	0	0	0	$-\frac{1}{2} - i\frac{\sqrt{3}}{2}$	0	$\frac{1}{2} - i\frac{\sqrt{3}}{2}$	$\frac{1}{2} - i\frac{\sqrt{3}}{2}$	0
	ψ_5^2	0	1	0	$\frac{1}{2} + i\frac{\sqrt{3}}{2}$	$\frac{1}{2} + i\frac{\sqrt{3}}{2}$	0	$-\frac{1}{2} + i\frac{\sqrt{3}}{2}$	0	0
	ψ_5^3	0	0	1	0	0	$-\frac{1}{2} - i\frac{\sqrt{3}}{2}$	0	0	$-\frac{1}{2} + i\frac{\sqrt{3}}{2}$
	ψ_5^4	0	-1	0	$-\frac{1}{2} + i\frac{\sqrt{3}}{2}$	$-\frac{1}{2} + i\frac{\sqrt{3}}{2}$	0	$\frac{1}{2} + i\frac{\sqrt{3}}{2}$	0	0
	ψ_5^5	-1	0	0	0	$\frac{1}{2} - i\frac{\sqrt{3}}{2}$	0	$-\frac{1}{2} - i\frac{\sqrt{3}}{2}$	$-\frac{1}{2} - i\frac{\sqrt{3}}{2}$	0
	ψ_5^6	0	0	1	0	0	$-\frac{1}{2} + i\frac{\sqrt{3}}{2}$	0	0	$-\frac{1}{2} - i\frac{\sqrt{3}}{2}$

REPRESENTATION ANALYSIS

One ends up with 9 different basis vectors (2 for Γ_2 , 1 for Γ_4 , and 6 for Γ_5)

Real basis for Γ_5 :

$$\tilde{\psi}_5^1 = iA\psi_5^1 + B_{++}\psi_5^2 + B_{-+}\psi_5^4 + iA\psi_5^5,$$

$$\tilde{\psi}_5^2 = B_{--}\psi_5^1 - iA\psi_5^2 - iA\psi_5^4 + B_{+-}\psi_5^5,$$

$$\tilde{\psi}_5^3 = C_+\psi_5^3 + C_-\psi_5^6,$$

$$\tilde{\psi}_5^4 = A\psi_5^1 + iB_{--}\psi_5^2 + iB_{-+}\psi_5^4 - A\psi_5^5,$$

$$\tilde{\psi}_5^5 = iB_{++}\psi_5^1 - A\psi_5^2 + A\psi_5^4 + iB_{+-}\psi_5^5,$$

$$\tilde{\psi}_5^6 = D_+\psi_5^3 + D_-\psi_5^6,$$

where $A = 1/\sqrt{3}$, $B_{\pm\pm} = (\pm 1 \pm i/\sqrt{3})/2$,

$C_{\pm} = (-\sqrt{3} \pm i)/4$, and $D_{\pm} = (1 \pm i/\sqrt{3})/\sqrt{8}$,

MAGNETIC STRUCTURE REFINEMENT

The output from the Baslreps, can be used as an input for FullProf

Magnetic structure should correspond to a single irreducible representation (IRR), yet it can be a combination of several basis vector corresponding to the same IRR

If the transition is of a first-order type this is not the case – everything is allowed

Show Fullprof

REFINEMENT RESULTS

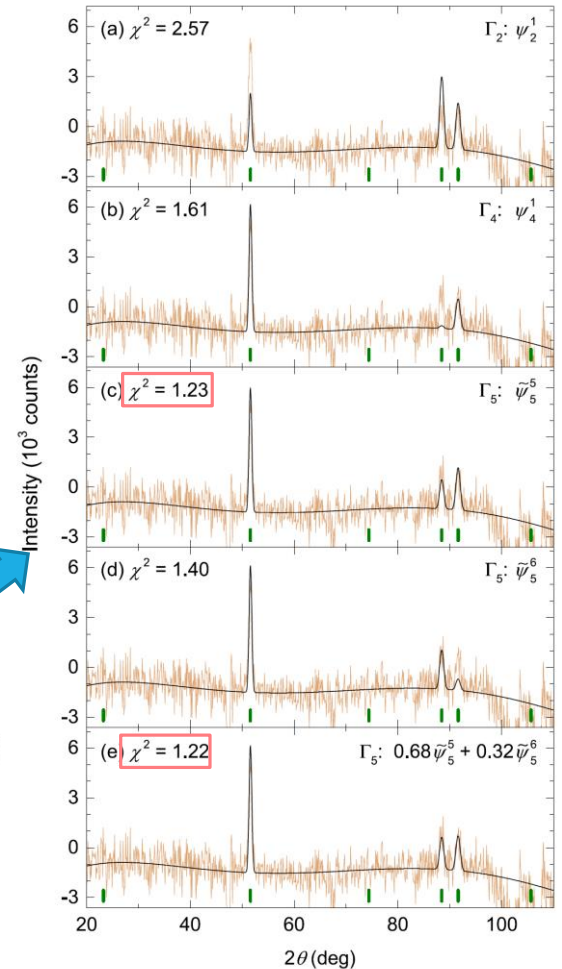

Refinement is typically performed separately for each IRR

Then the results are compared

First criteria is the quality of the refinement $\rightarrow \chi^2$

Second is the physical relevance

Considering antiferromagnetic interaction and potential strength of anisotropies we found that the more likely solution corresponds to the ψ_5^5 basis vector

EXAMPLE: β -TeVO₄

Starting point

- Crystal structure
- Basic magnetic properties ($V^{4+} S = 1/2$)
- Magnetic ordering at 4.6 K

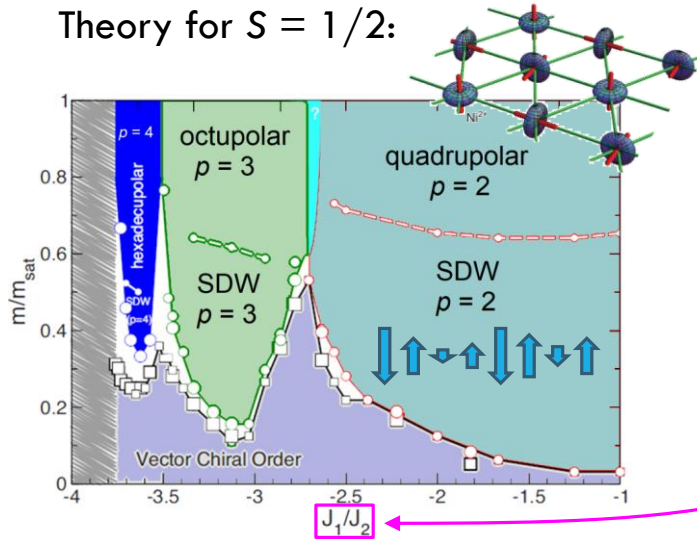

Our approach to determine the magnetic order

- **Experiment:** Powder neutron diffraction to see if long-range magnetic order develops
- **Analysis:** Indexation of magnetic reflections, attempt to refine the magnetic structure – *inconclusive*
- **Experiment:** Single crystal diffraction to resolve magnetic wave vector and collect magnetic reflections
- **Analysis:** Refinement of magnetic structure – *inconclusive*
- **Experiment:** Polarized neutron scattering – resolv between colinear and spiral
- **Experiment:** Single-crystal inelastic neutron scattering on tripe axis spectrometer
- **Analysis:** Modelling of spin-wave excitations

J. Sudan et al., *Phys. Rev. B* **80**, 140402(R) (2009).

Theory for classical spin:

R. Bursill et al., *J. Phys.: Condens. Mater* **7**, 8605 (1995)

β -TeVO₄ – MAGNETIC SUSCEPTIBILITY

Initial modeling: a simple spin chain model with AFM interactions $J = 21.4$ K.

Significantly smaller Curie-Weiss temperature $\theta = 1.6$ -4.4 K.

Interactions of different signs?

At low temperatures several magnetic transitions exist:

$T_{N1} = 4.65$ K, $T_{N2} = 3.28$ K, $T_{N3} = 2.26$ K

This indicates the existence of several energetically almost equivalent magnetic states.

Magnetic frustration!

Field direction	Curie-Weiss temp θ (K)	g -value for the V ⁴⁺ ion
$H b$	+4.418	2.027
$H a$ ($H \perp b$)	+1.598	1.962
$H c$ ($H \perp b$)	+1.658	1.965

Savina et al. PRB **84**, 104447 (2011).

POWDER NEUTRON DIFFRACTION

At 4.4 K new reflections occur.

At 3.0 K potential very weak reflections appear

Some of these seem to disappear below 2.3 K

These temperatures are in line with anomalies in susceptibility:

$T_{N1} = 4.65$ K, $T_{N2} = 3.28$ K, $T_{N3} = 2.26$ K

The position of the stronger three reflections changes continuously with temperature – implying incommensurate magnetic order.

Below 2.3 K the intensity and position of the reflections appears to saturate.

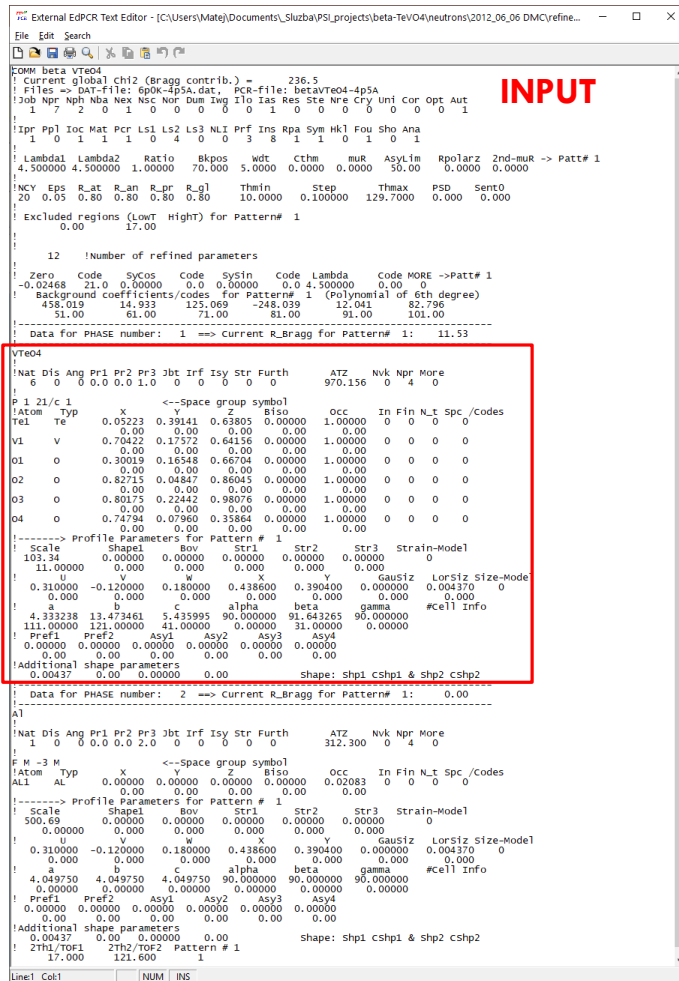

CRYSTAL STRUCTURE REFINEMENT

Refinement of **crystal structure** above the transition (at 20 K) to check the quality of the sample (potential impurities, crystallinity, ...).

Based on known crystal structure, we adjust the *.pcr file:

Starting from working file, we insert new space group, lattice parameters, new atoms and positions. see FullProf manual

CRYSTAL STRUCTURE REFINEMENT

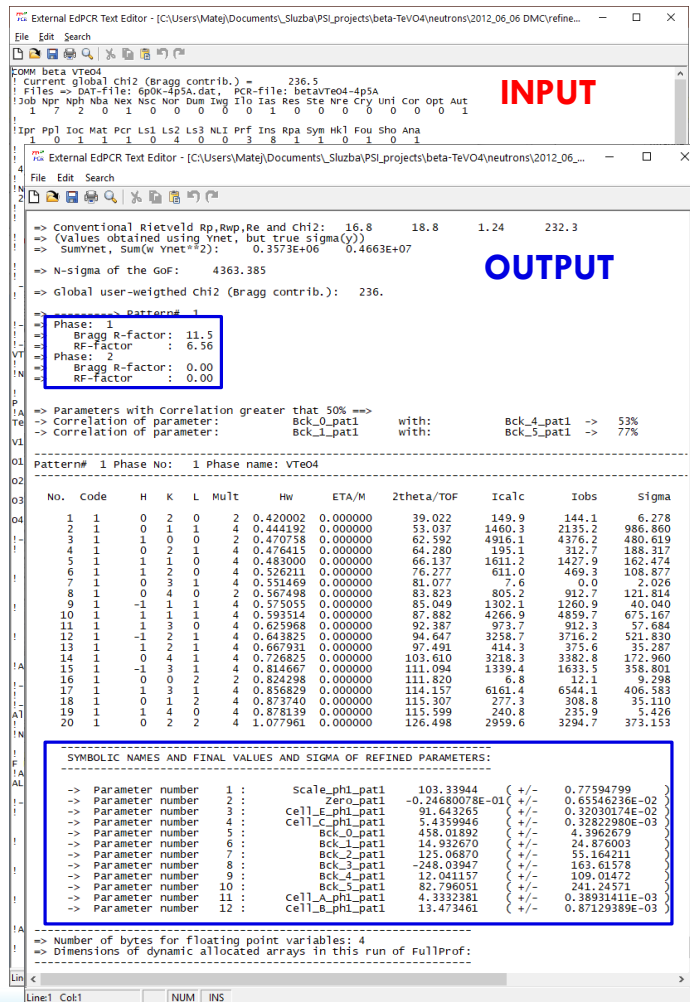

Refinement of **crystal structure** above the transition (at 20 K) to check the quality of the sample (potential impurities, crystallinity, ...).

Based on known crystal structure, we adjust the *.pcr file:

Starting from working file, we insert new space group, lattice parameters, new atoms and positions. **see FullProf manual**

In the refinement we free the parameters slowly – first unit cell, then background, then strong scattering atoms (be careful with vanadium), ...

The refinement output can be seen in the *.out file, while for visualisation WinPLOTER is used.

MAGNETIC STRUCTURE REFINEMENT — POWDER

Irreducible representations determine possible magnetic moment components and determine how are these related between different magnetic atoms — **output of *Baslreps***

Each representation demands a separate *FullProf* treatment, i.e., a separate *.pcr file.

Baslreps provides a symmetry related part for the *.pcr file for the magnetic structure refinement with the *FullProf*.

Powder refinement inconclusive

SINGLE-CRYSTAL DIFFRACTION

Single crystal has to be aligned precisely to Bragg reflection

1. step: 2θ is set for the strongest $(h\ 0\ 0)$, $(0\ k\ 0)$ or $(0\ 0\ l)$
2. step: this crystal axis is by eye aligned to bisect the incident and scattered beam, i.e., pointing along Q vector
3. step: crystal is rotated until the detector detect intensity
4. step: centre and proceed to next reflection
- ...
- (n - 1). step: index the reflections – based on the angles calculate possible (h, k, l)
- n. step: after collecting several reflections along all three crystal axes, one can refine the U-matrix, connecting the reciprocal space with ϕ, χ , and ω angles

Having the U matrix, a large number of reflections can be scanned, which can then be used for the refinement.

RESULTS AT THE END OF THE LAST CYCLE (no : 3)

SINGLE-CRYSTAL DIFFRACTION

A list of reflections can be generated either by FullProf or by some other program.

After measurements a batch fit can be applied to the collected data.

The results need to be inspected if there are some anomalies – split reflections, misalignment, ...

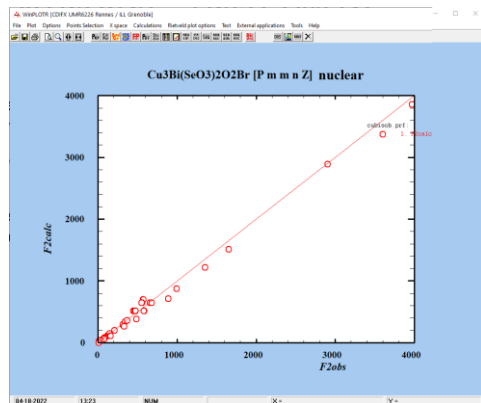

STRUCTURE REFINEMENT – SINGLE CRYSTAL

Similar to powder, except that instead of profile matching the input for the program is now a list of integrated intensities.

The intensities must be determined from “ ω scans” – rotation of the sample perpendicular to the scattering plane at fixed 2θ .

The integrated intensities must be corrected for the Lorentz factor, i.e., multiplied by $\sin(2\theta)$, due to angular range during which the reflection is reflecting into detector.

Show FullProf sample

SINGLE-CRYSTAL DIFFRACTION - $\beta\text{-TeVO}_4$

At TriCS and TASP instruments, at PSI, Switzerland

$$\mathbf{k} = (h, 0, l)$$

$$\mathbf{k} + \Delta\mathbf{k} = (h + \Delta h, 0, l + \Delta l)$$

Scan along special reciprocal direction demands rotation of several motors simultaneously!

MAGNETIC ORDERS AT ZERO FIELD

Modulation along the chain matches the classical pitch angle for $J_1/J_2 = -1.25$.

$\mathbf{k} \rightarrow \lambda'$
SDW^(ac)

$\mathbf{k} + \Delta\mathbf{k} \rightarrow \lambda' + \Delta\lambda'$
SDW^(b)

POWDER INELASTIC SCATTERING – β -TeVO₄

To obtain an overview of excitations one typically begins with measurements on powder samples

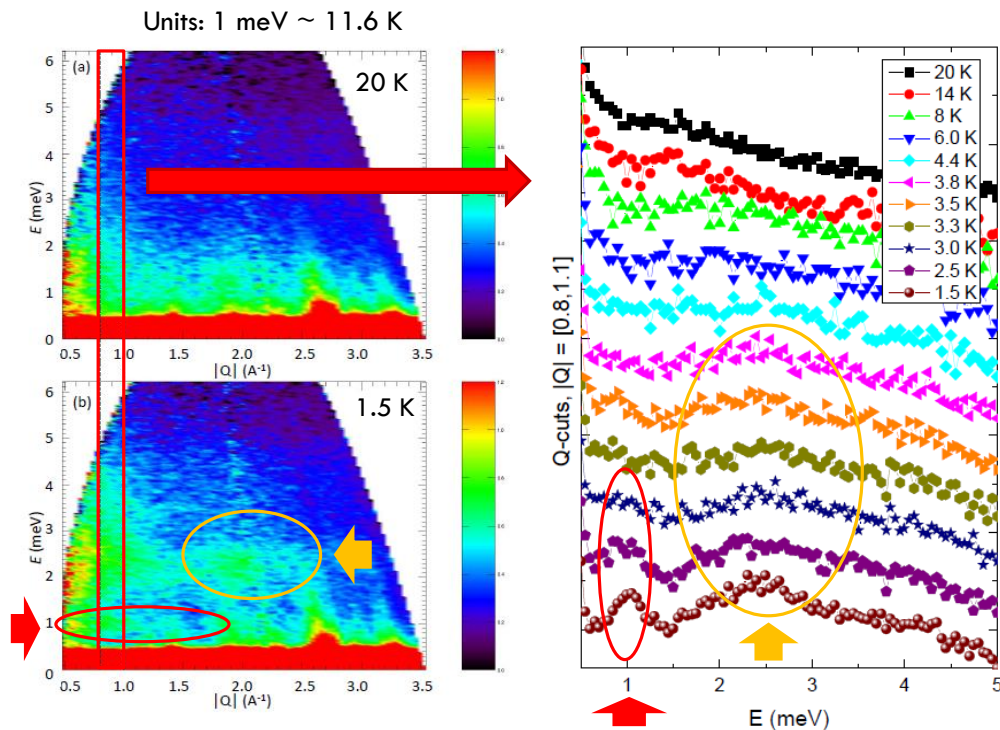

The energy range is chosen based on the knowledge of the main exchange interaction

Similar to diffraction one typically measure Energy-Q map above and below the magnetic transition

Magnetic excitations are rather weak hence they are typically measured at lowest temperatures

The excitations may persist significantly above the ordering temperature

Powder data are rarely sufficient for precise determination of the spin Hamiltonian \rightarrow for this, single crystal measurements are preferable.

SINGLE-CRYSTAL INELASTIC SCATTERING – β -TeVO₄

Single crystals measurements are typically performed on Triple Axis Spectrometer

Due to weak signal often several crystals need to be aligned before the experiment (larger crystals are often unavailable)

For mounting one should use as little material as possible (preferably Al) and avoid glues, which typically contain hydrogen (strong incoherent scatterer)

All the crystals should be as close as possible

The resolution is dictated by the precision of the alignment (~ 1 -3 deg)

Real space

Reciprocal space

a and c are in the scattering plane

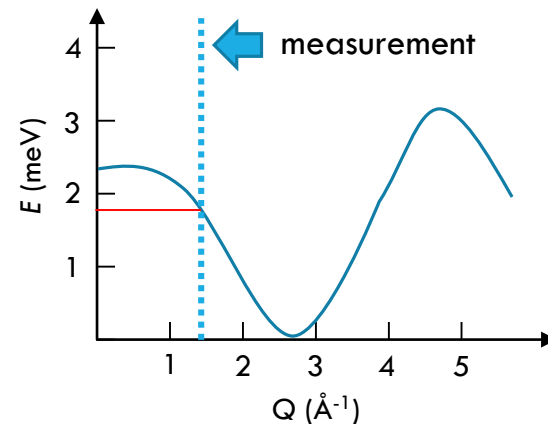

TRIPLE AXIS SPECTROMETER

Constant Q measurements

\vec{Q} is kept constant, while changing \vec{k}_i and \vec{k}_f , i.e., while changing the energy transport $E = \hbar\omega$

$$\hbar\omega = E_i - E_f = \frac{\hbar^2}{2m}(k_i^2 - k_f^2)$$

$$\vec{Q} = \vec{k}_i - \vec{k}_f$$

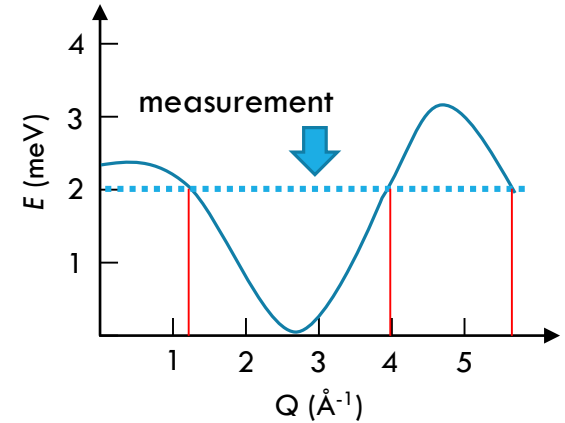

TRIPLE AXIS SPECTROMETER

Constant E measurements

\vec{Q} is being changed while keeping $E = \hbar\omega$

$$\hbar\omega = E_i - E_f = \frac{\hbar^2}{2m} (k_i^2 - k_f^2)$$

$$\vec{Q} = \vec{k}_i - \vec{k}_f$$

TRIPLE AXIS SPECTROMETER

Due to experimental limitations \mathbf{Q} and E , i.e., ω , are defined only to a certain level of precision

Reducing these uncertainties leads to a **better resolution** **BUT** it also leads to **lower counts**

Resolution ellipsoid: resolution volume, with distinct orientations in (\vec{Q}, E) space

β -TeVO₄ RESULTS

$J \sim 20 \text{ K} \sim 2 \text{ meV}$

(1 meV = 11.6 K)

β -TeVO₄ RESULTS

$J \sim 20 \text{ K} \sim 2 \text{ meV}$

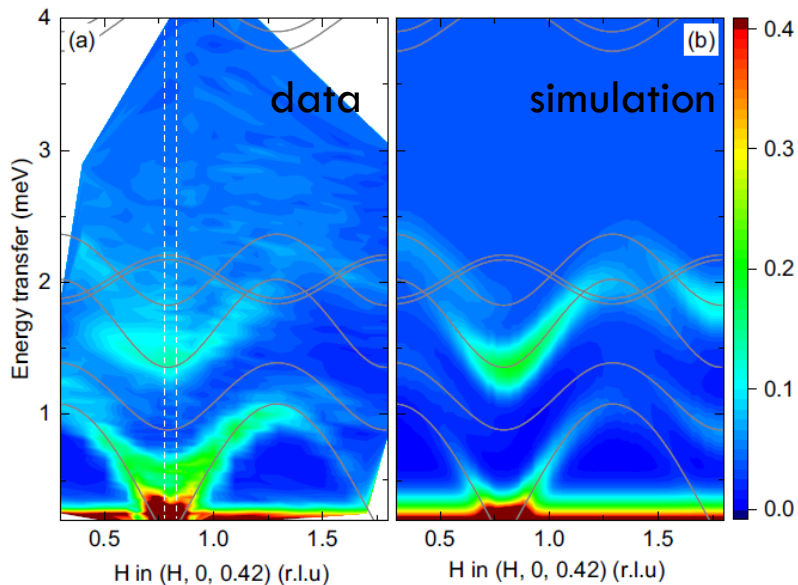

(1 meV = 11.6 K)

ANALYSIS – β -TeVO₄

Inelastic neutron scattering at 1.7 K and 0 T.

$$\begin{aligned}
 H = & J_1 \sum_{n,j} (\mathbf{S}_{n,j} \cdot \mathbf{S}_{n,j+1} + \delta_1^b S_{n,j}^b S_{n,j+1}^b + \delta_1^c S_{n,j}^c S_{n,j+1}^c) \\
 & + J_2 \sum_{n,j} (\mathbf{S}_{n,j} \cdot \mathbf{S}_{n,j+2} + \delta_2^b S_{n,j}^b S_{n,j+2}^b + \delta_2^c S_{n,j}^c S_{n,j+2}^c) \\
 & + J_3 \sum_{\langle n,m \rangle, j} \mathbf{S}_{n,j} \cdot \mathbf{S}_{m,j-1} + J_4 \sum_{\langle n,m' \rangle, j} \mathbf{S}_{n,j} \cdot \mathbf{S}_{m',j+1}, \quad (1)
 \end{aligned}$$

$\mathbf{k}_{IC} = (-0.208, 0, 0.419)$ and magnetic moments lying in the ac plane. The corresponding parameters are $J_1 = -38$ K, $J_2 = 38$ K, $J_3 = 3$ K, $J_4 = -1.9$ K, $\delta_1^b = 0.106$, $\delta_2^b = -0.126$, $\delta_1^c = 0.01$, and $\delta_2^c = 0.01$, uncertainty of $\sim 5\%$ for J_i ($i = 1-4$), $\sim 20\%$ for δ_i^b ($i = 1,2$), and $\sim 50\%$ for δ_i^c ($i = 1,2$).

TRINAGULAR ANTIFERROMAGNET $\text{NdTa}_7\text{O}_{19}$

Rare earth: $\text{Nd}^{3+} (4f_{9/2})$

Crystal electric field levels:

BULK MAGNETIC PROPERTIES

Nd^{3+} f-electrons: highly localized orbitals.

Interactions of several Kelvins are expected.

No magnetic order down to 2 K.

Magnetism at higher temperatures is defined by crystal-electric-field (CEF) levels.

INELASTIC NEUTRON SCATTERING (INS)

Time-of-flight method at MARI instrument at ISIS source, UK.

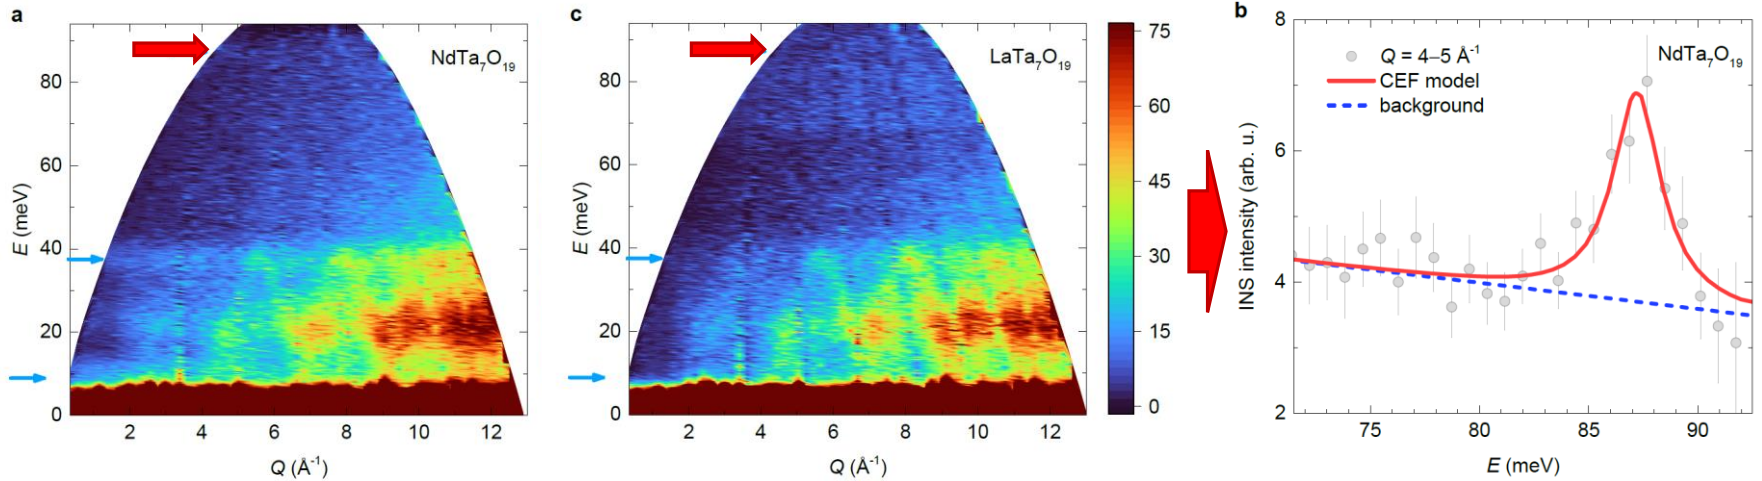

Measurements on magnetic ($\text{NdTa}_7\text{O}_{19}$) and non-magnetic ($\text{LaTa}_7\text{O}_{19}$) powders at 5 K.

Difference between the two yields magnetic signal – two flat levels.

No dispersion – single-ion property. Intensity goes down with Q – magnetic signature.

INELASTIC NEUTRON SCATTERING (INS)

Same measurements performed with higher incident-neutron energies.

Additional flat level at higher-energies.

CRYSTAL ELECTRIC FIELD REFINEMENT

Combined refinement of INS, susceptibility and magnetization results. Program PHI (<https://www.nfchilton.com/phi.html>) and/or Mantid.

A single solution for CEF levels – energy levels and magnetic states.

Magnetic ground state is of Ising type – magnetic moment perpendicular to the plane (along the c axis) is dominant.

$$g \text{ factors } g_z = 2.78 \text{ and } g_{xy} = 1.22$$

GROUND STATE

CEF model does not account for complete $M(H)$ at lowest temperature of 2 K

Comparison of neutron diffraction (WISH at ISIS) at 40 mK and 10 K imply potential presence of diffuse magnetic scattering.

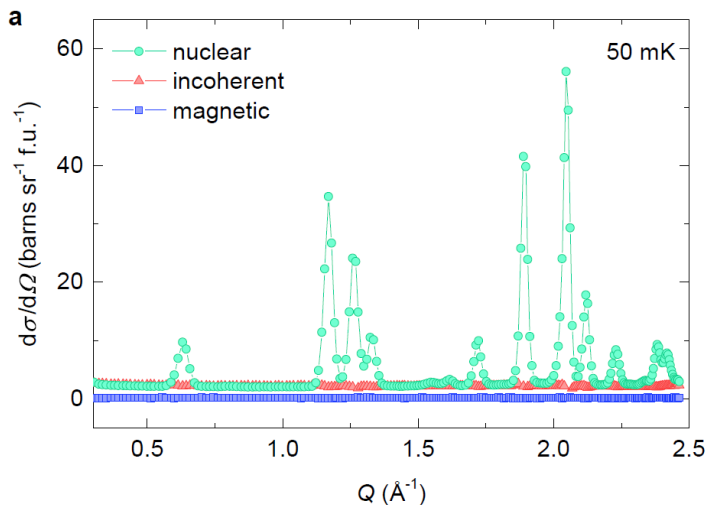

POLARIZED NEUTRON SCATTERING

At D7 instrument at ILL, France.

Directly distinguish magnetic and non-magnetic contribution – no need for subtraction.

Reveal magnetic nearest-neighbour Ising correlations at 50 mK.

T. Arh *et al.* Nat. Matter. 21, 416, 2022

SUMMARY

Basic neutron advantages:

- Wavelength and kinetic energy comparable with interatomic spacings and excitations in solids
- Weak interaction with matter - convenient for scattering, simple interpretation
- Neutron magnetic moment couples to magnetic field - neutron “sees” magnetism

Magnetic scattering by unpaired electron spins

- Both spin and orbital angular momentum of electrons contribute
- Magnetic interactions are long range and non-central - neutrons can be used to probe electron distributions
- Nuclear and magnetic scattering have similar magnitudes
- Magnetic scattering depends only on component of B perpendicular to Q
- Polarized neutrons are sensitive to a particular magnetization direction

Inelastic neutron scattering reveals details of the shapes of interaction potentials in materials
